

## Charge Pump DC-to-DC Lower Power Voltage Converter

### FEATURES

- Zero  $I_Q$  Current During Shutdown
- Converts +5V Logic Supply To.....  $\pm 5$  System
- Wide Input Voltage Range ..... 1.2V To 12V
- Low Power Supply ..... 80 $\mu$ A
- Efficient Voltage Conversion ..... 99.9%
- RS232 Negative Power Supply
- Low Cost, Simple To Use
- Available In Standard 8 Pin Low Cost SOIC &  $\mu$ SOIC™
- ESD Protection Up To..... 3KV
- Similar To Industry Standard ICL7660

### APPLICATIONS

- -5 Volts For LCD
- A-To-D Converters
- D-To-A Converters
- Multiplexers
- Operational Amplifiers

### PRODUCT DESCRIPTION

The ALPHA Semiconductor AS7660G DC-to-DC converter will generate a negative voltage from a positive source. Includes internal shut down to save power in Battery Operating Applications. The AS7660G generates -5V in +5V digital systems and with two external capacitors, the device will convert a 1.2V to 12V input signal to a -1.2V to -12V level. AS7660G input can also be as low as 1.0V by connecting LV to Ground.

AS7660G chip contains a DC Power Supply Regulator, RC Oscillator, Voltage-Level Transistor, Four Output Power MOS Switches, and a unique logic element which ensures latch-up free operation.

The Oscillator, when unloaded, oscillates at a nominal frequency of 10KHZ for input voltage for 5 volts. The frequency can be lowered by the addition of an external capacitor to the OSC terminal, or the Oscillator maybe overdriven by an external clock.

Applications include analog-to-digital converters, digital-to-analog converters, operational amplifiers and multiplexers. Many of these systems require negative supply voltages. The AS7660G allows +5V digital logic systems to incorporate these analog components without an additional main power source. Lower part count, less real estate, ease of use are just a few of the benefits of the AS7660G. ALPHA Semiconductor is the only manufacture to AS7660G in the very small  $\mu$ SOIC™.

## CIRCUIT DESCRIPTION

The AS7660G contains all the necessary circuitry to complete a voltage doubler, with the exception of two external capacitors, which may be inexpensive 10 µF polarized electrolytic capacitors. Operation is best understood by considering Figure 2, which shows an idealized voltage doubler. Capacitor  $C_1$  is charged to a voltage,  $V^+$ , for the half cycle when switches  $S_1$  and  $S_3$  are closed. (Note: Switches  $S_2$  and  $S_4$  are open during this half cycle.) During the second half cycle of operation, switches  $S_2$  and  $S_4$  are closed, with  $S_1$  and  $S_3$  open, thereby shifting capacitor  $C_1$  negatively by  $V^+$  volts. Charge is then transferred from  $C_1$  to  $C_2$ , such that the voltage on  $C_2$  is exactly  $V^+$ , assuming ideal switches and no load on  $C_2$ .

The four switches in Figure 2 are MOS power switches,  $S_1$  is a P-channel device, and  $S_2$ ,  $S_3$  and  $S_4$  are N-channel devices. The main difficulty with this approach is that in integrating the switches, the substrates of  $S_3$  and  $S_4$  must always remain reverse-biased with respect to their sources, but not so much as to degrade their ON resistances. In addition, at circuit start-up, and under output short circuit conditions ( $V_{OUT} = V^+$ ), the output voltage must be sensed and the substrate bias adjusted accordingly. Failure to accomplish this will result in high power losses and probable device latch-up.

This problem is eliminated in the AS7660G by a logic network which senses the output voltage ( $V_{OUT}$ ) together with the level translators, and switches the substrates of  $S_3$  and  $S_4$  to the correct level to maintain necessary reverse bias.

Figure 2. Idealized Switched Capacitor

The voltage regulator portion of the AS7660G is an integral part of the anti-latch-up circuitry. Its inherent voltage drop can, however, degrade operation at low voltages. To improve low-voltage operation, the LV pin should be connected to GND, disabling the regulator. For supply voltages greater than 3.5V, the LV terminal must be left open to ensure latch-up-proof operation and prevent device damage.

## THEORETICAL POWER EFFICIENCY CONSIDERATIONS

In theory, a voltage multiplier can approach 100% efficiency if certain conditions are met:

1. The drive circuitry consumes minimal power.
2. The output switches have extremely low ON resistance and virtually no offset.
3. The impedances of the pump and reservoir capacitors are negligible at the pump frequency.

The AS7660G approaches these conditions for negative voltage multiplication if large values of  $C_1$  and  $C_2$  are used. Energy is lost only in the transfer of charge between capacitors if a change in voltage occurs. The energy lost is defined by:

$$E = 1/2 C_1 (V_1^2 - V_2^2)$$

$V_1$  and  $V_2$  are the voltages on  $C_1$  during the pump and transfer cycles. If the impedances of  $C_1$  and  $C_2$  are relatively high at the pump frequency (refer to Figure 2), compared to the value of  $R_L$ , there will be a substantial difference in voltages  $V_1$  and  $V_2$ . Therefore, it is not only desirable to make  $C_2$  as large as possible to eliminate output voltage ripple, but also to employ a correspondingly large value for  $C_1$  in order to achieve maximum efficiency of operation.

## DOS AND DON'TS

- Do not exceed maximum supply voltages.
- Do not connect LV terminal to GND for supply voltages greater than 3.5V
- Do not short circuit the output to  $V^+$  supply for voltages above 5.5V for extended periods; however, transient conditions including start up are okay.
- When using polarized capacitors in the inverting mode, the + terminal of  $C_1$  must be connected to pin 2 of the AS7660G and the - terminal of  $C_2$  must be connected to GND Pin 4.

## SIMPLE NEGATIVE VOLTAGE CONVERTER

Figure 3 shows typical connections to provide a negative supply where a positive supply is available. A similar scheme may be employed for supply voltages anywhere in the operation range of + 1.2V to +12V, keeping in mind that pin 6 (LV) is tied to the supply negative (GND) only for supply voltages below 3.5V.

The output characteristics of the circuit in Figure 3 are those of a nearly ideal voltage source in series with  $70\Omega$ . Thus, for a load current of -10 mA and a supply voltage of +5V, the output voltage would be -4.3V.

The dynamic output impedance of the AS7660G is due, primarily, to capacitive reactance of the charge transfer capacitor ( $C_1$ ). Since this capacitor is connected to the output for only 1/2 of the cycle, the equation is:

$$X_C = \frac{1}{2\pi f C_1} = 3.18\Omega$$

where  $f = 10 \text{ kHz}$  and  $C_1 = 10\mu\text{F}$ .

\*NOTES:  $V_{OUT} = -n V^+$  for  $1.2V \leq V^+ \leq 12V$

## PARALLELING DEVICES

Any number of AS7660G voltage converters may be paralleled to reduce output resistance (Figure 4). The reservoir capacitor,  $C_2$ , serves all devices, while each device requires its own pump capacitor,  $C_1$ . The resultant output resistance would be approximately:

$$R_{OUT} = \frac{R_{OUT} \text{ (of AS7660G)}}{n \text{ (number of devices)}}$$

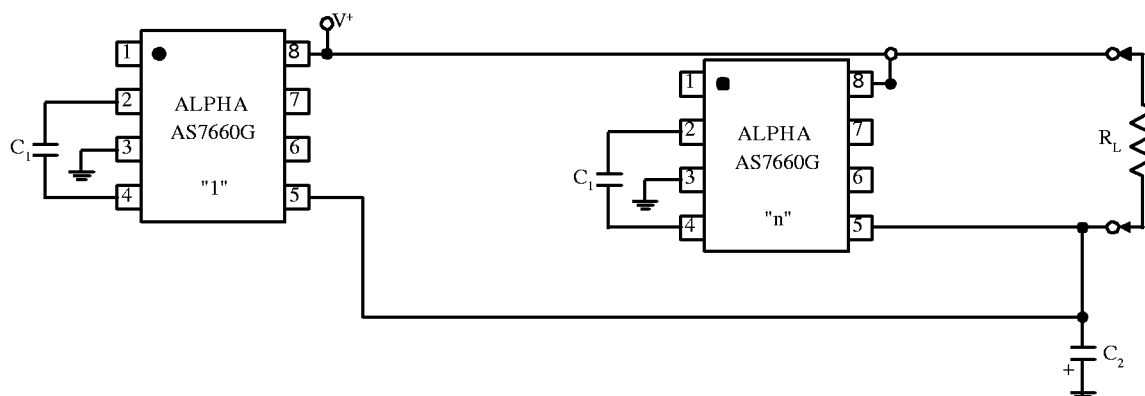

Figure 4. Paralleling Devices Lowers Output Impedance

## CASCADING DEVICES

The AS766G may be cascaded as shown (Figure 6) to produce larger negative multiplication of the initial supply voltage. However, due to the finite efficiency of each device, the practical limit is 10 devices for light loads. The output voltage is defined by:

$$V_{OUT} = -n (V_{IN})$$

where  $n$  is an integer representing the number of devices cascaded. The resulting output resistance would be approximately the weighted sum of the individual AS7660G  $R_{OUT}$  values.

## CHANGING THE AS7660G OSCILLATOR FREQUENCY

It may be desirable in some applications (due to noise or other considerations) to increase the oscillator frequency. This is achieved by overdriving the oscillator from an external clock, as shown in Figure 6. In order to prevent possible device latch-up, a 1 kΩ resistor must be used in series with the clock output. In a situation where the designer has generated

the external clock frequency using TTL logic, the addition of a 10 kΩ pull-up resistor to  $V^+$  supply is required. Note that the pump frequency with external clocking, as with internal clocking, will be 1/2 of the clock frequency. Output transitions occur on the positive-going edge of the clock.

It is also possible to increase the conversion efficiency of the AS7660G at low load levels by lowering the oscillator frequency. This reduces the switching losses, and is achieved by connecting an additional capacitor,  $C_{OSC}$ , as shown in figure 7. Lowering the oscillator frequency will cause an undesirable increase in the impedance of the pump ( $C_1$ ) and the reservoir ( $C_2$ ) capacitors. To overcome this, increase the values of  $C_1$  and  $C_2$  by the same factor that the frequency has been reduced. For example, the addition of a 100 pF capacitor between pin 7 (OSC) and pin 8 ( $V^+$ ) will lower the oscillator frequency to 1 kHz from its nominal frequency of 10 kHz (a multiple of 10), and necessitate a corresponding increase in the values of  $C_1$  and  $C_2$  (from 10 F to 100µF).
