6 BIT 384 CHANNEL RSDS TFT-LCD SOURCE DRIVER

Nov. 2002.

Ver. 0.2

INTRODUCTION

The S6C1108 is a Source Driver suitable for Reduced Swing Differential Signaling(RSDS) digital interface. It converts 18-bit digital data into the analog voltage for 384 channels, charging each sub-pixel to the correct gray level corresponding to the digital value.

The RSDS path to the panel timing controller contributes toward lowering radiated EMI, reducing system power consumption and eliminates one of the two pixel busses used in typical XGA, SXGA TFT LCD panels. This single 9-bit differential bus conveys the 18-bit color data for XGA, SXGA panels.

OPERATION DESCRIPTION

RSDS RECEIVER AND DEMUX

The S6C1108 adapts the RSDS interface for EMI solution. The internal RSDS receiver block operates the comparison between the transmitted differential input pair data. The input data lines from the timing controller to the RSDS receiver consist of 6-bit digital, 3 colors, 1 port, 2 differential pairs(DxxP/DxxN).

The input common mode voltage range at the RSDS receiver is 1.2V. The differential data and clock signals from the panel timing controller arrive at the S6C1108 as multiplexed, even and odd data fields. (i.e., the data is 2:1 multiplexed). The nominal peak to peak swing of this data is 200mV across a termination resistor.

RSDS DATA BUS INTERFACE CONTROL

DATPOL controls the internal data inversion. When DATPOL="H", the internal data is inverted. The inverted data is the same that the RSDS receiver operates the comparison between the cross-transmitted differential input pair data. Using the data inversion input pin, DATPOL, the RSDS data bus interface can be changed.

DISPLAY DATA TRANSFER

When DIO1 (or DIO2) pulse is loaded into the internal latch on the falling edge of CLKP, DIO1 (or DIO2) pulse enables the operation of data transfer, so display data is valid on the 2nd falling edge of CLKP. Once all the data of 384 channels is loaded into internal latch, it goes into stand-by state automatically, and any new data is not accepted even though CLKP is provided until next DIO1 (or DIO2) input. When next DIO1 (or DIO2) is provided, new display data is valid on the 2nd falling edge of CLKP after the rising edge of DIO1 (or DIO2).

EXTENSION OF OUTPUT

Output pin can be adjusted to an extended screen by cascade connection.

When SHL="L", Connect DIO1 pin of the previous stage to the DIO2 pin of the next stage and all the input pins except DIO1 and DIO2 are connected together in each device.

When SHL="H", Connect DIO2 pin of the previous stage to the DIO1 pin of the next stage and all the input pins except DIO2 and DIO1 are connected together in each device.

RELATIONSHIP BETWEEN INPUT DATA VALUE AND OUTPUT VOLTAGE

The LCD drive output voltages are determined by the input data and 14 (7 by 2) gamma corrected power supplies (VGMA1 to VGMA14). Besides, to be able to deal with dot line inversion when mounted on a single-side, gradation voltages with different polarity can be output to the odd number output pins and the even number output pins. Among 7-by-2 gamma corrected voltages, input gray-scale voltages of the same polarity with respect to the common voltage, for the respective 7 gamma corrected voltages of VGMA1 to VGMA7 and VGMA8 to VGMA14.

Total R : 14823 Ω 

The S6C1108 has on-chip dividing resistors.

The gamma correction voltage input pins are divided into two parts. Each part is connected in series with resistors. Each of these resistor series has a total typical value of 14823 Ω .

Note that since these voltages are resistor divided internally, the voltages applied to the VGMA_n pins should be applied through a low-impedance circuit.

If the voltages are directly applied by the resistor divider, the desired output voltages may not result (Recommend you to use operational amplifier).

CAUTIONS:

If LSIs are stressed beyond those listed above “absolute maximum ratings”, they may be permanently destroyed. These are stress ratings only, and functional operation of the device at these or any other condition beyond those indicated under “recommended operating conditions” is not implied. Exposure to absolute maximum rated conditions for extended periods may affect device reliability.

Turn on power order: VDD1 → control signal input → VDD2 → VGMA1 to VGMA14

Turn off power order: VGMA1 to VGMA14 → VDD2 → control signal input → VDD1
